Plano Reports Sanitary Sewer Overflow

The City of Plano is reporting another sanitary sewer overflow from a City manhole in the area of Glen Eagles Golf Course. The estimated overflow volume was 100,000 gallons at 2:00pm. The wastewater is flowing into White Rock Creek. Once the flow is contained, Plano Public Works Department personnel will walk the creek to verify no adverse effects to water or aquatic life. They are monitoring the overflow around the clock and will be performing clean-up of the affected area once the overflow is stopped. Although the City of Plano has experienced this overflow of domestic wastewater, the public drinking water is not affected and continues to be safe for consumption.

This is the third overflow in the last week at the same location. On Tuesday, 159,900 gallons of wastewater/rainwater flowed into the creek. Another overflow on Saturday spilled 174,180 into the creek.

Sanitary Sewer Overflows

Sanitary Sewer overflows sometimes occur when we have significant rain events. The problems are the results of “inflow” and “infiltration” of rainwater. Inflow occurs when storm water flows into the sanitary sewage system through damaged system components and illegal connections such as yard drains or downspouts. Infiltration occurs when groundwater seeps into the sewage system through defects such as holes and cracks in manholes and sewer pipes.

City of Plano public works crews respond to the overflows as quickly as possible to begin the cleanup process. If the spill enters a creek, those crews routinely walk along the creek searching for any debris, which if found, is immediately removed. They also search for signs of fish kills. In most cases, the sewage is quickly diluted not only by the water that seeped into the line, but also rushing waters of the creeks fueled by runoff/flooding.

While the sanitary sewer system is designed to handle some inflow and infiltration, when it is excessive, as during our recent rains, the system’s capacity is exceeded, resulting in overflows.

The City has an Inflow/Infiltration Reduction Program to identify and alleviate sources of infiltration and inflow. Crews conduct flow checks to identify pipes with a significant increase in flow during heavy rains. They also use cameras to inspect sewer pipes and identify cracks. We also use smoke and dye testing to identify sources of inflow and infiltration. When the City identifies these sources, repairs are completed as soon as possible.
